Congratulations! You passed!
Grade received 100%To pass 80% or higher

### 1. Activity overview

By now, you've been introduced to some useful techniques for cleaning spreadsheet data, such as sorting and filtering. In this activity, you'll continue to develop your data-cleaning skills by using spreadsheet functions.

Imagine you are a data analyst working for a marketing agency based in San Francisco. The marketing agency wants to contact local boba tea shops to inquire about a potential collaboration for a new marketing campaign. The agency plans to visit the top-rated shops within a 10-mile radius of the center of their target area. To assist with planning, the agency asks your team to review external data related to ratings and locations of boba tea shops in San Francisco. One of your teammates has created a spreadsheet from an online source. However, the data is not in the greatest shape.

Your assignment is to identify the dirty elements in the dataset and clean them up.

By the time you complete this activity, you will be able to identify dirty elements in a dataset, remove duplicate data, and use the COUNTIF and SPLIT functions to help clean data.

What you will need

The dataset includes the following column headers:

Column Header	Description	
id	unique identifier for each boba shop	
name	name of boba shop	
rating	Yelp rating (0 to 5 stars)	
address	street address	
city	city	
lat-long	latitude and longitude	

To get started, access the spreadsheet that contains the data. Click the link and make a copy of the <u>spreadsheet</u> ☐. Or, if you don't have a Google account, you may download the dataset directly from the attachment below:

### Identify the dirty elements in your data

As a data analyst, your job is to present data that is readable, accurate, and visually appealing. Cleaning your data helps you achieve this goal. The first step is to identify the dirty elements in your data.

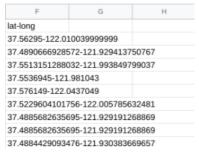

- 1. Rename your spreadsheet. Click Untitled Spreadsheet and enter a new name. You can use the name sf\_boba\_tea\_shop\_data or a similar name that describes the data your spreadsheet contains.
- 2. If you want to get a better view of your data, you can make the columns wider by dragging the right boundary of the column heading. This may apply to the name (B), address (D), and lat-long (F) columns.
- 3. Now, review your data and consider any problems you may need to address. The following are examples of errors that you can quickly identify and fix. This is not a comprehensive list of every potential problem, but is a great starting point for data cleaning.
- First, there is at least one duplicate line (rows 20 and 21) in your dataset.

21 17 mandro-teahouse-newark-3 4 34956 Newark Blvd Newark 37.5515049151237-122.05027218750	20	17	mandro-teahouse-newark-3	4	34956 Newark Blvd	Newark	37.5515049151237-122.050272187505
	21	17	mandro-teahouse-newark-3	4	34956 Newark Blvd	Newark	37.5515049151237-122.050272187505

• Second, all Yelp ratings should fall between 0 and 5. However, at least one rating (in cell C8) falls outside of that range.

	A	В	С	D	E	F
1	id	name	rating	address	city	lat-long
2	0	99-tea-house-fremont-2	4.5	3623 Thornton Ave	Fremont	37.56295-122.010039999999
3	1	one-tea-fremont-2	4.5	46809 Warm Springs Blvd	Fremont	37.4890666928572-121.929413750767
4	2	royaltea-usa-fremont	4	38509 Fremont Blvd	Fremont	37.5513151288032-121.993849799037
5	3	teco-tea-and-coffee-bar-fremont	4.5	39030 Paseo Padre Pkwy	Fremont	37.5536945-121.981043
6	4	t-lab-fremont-3	4	34133 Fremont Blvd	Fremont	37.576149-122.0437049
7	5	q-tea-monster-newark	4	39181 Cedar Blvd	Newark	37.5229604101756-122.005785632481
8	6	gong-cha-fremont	6.7	46827 Warm Springs Blvd	Fremont	37.4885682635695-121.929191268869

• Finally, the data for latitude and longitude is contained in a single column (F). In order for someone to be able to use this data for analysis, the two values should be in separate columns.

Now you know what issues to focus your attention on during the cleaning process.

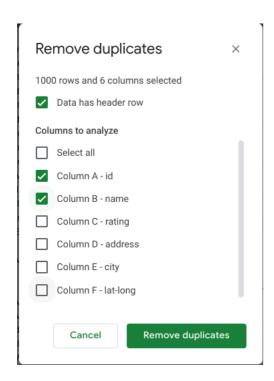

### Clean your data

Your goal is to fix these errors and help create a clean dataset for analysis. You can address each issue in turn.

#### Remove duplicates

The first step is to eliminate any duplicate entries from your dataset. As a best practice, duplicates should be removed even if they are not readily apparent.

- 1. To start, select columns A through F.
- 2. Then, in the menu bar, choose Data, then Data Cleanup, and select Remove duplicates.
- 3. In the pop-up window, click Data has header row. You want to remove duplicate boba shop id's and boba shop names. In the Columns to analyze section, make sure the relevant columns (id, name) are selected.

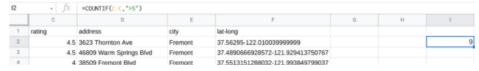

- 4. Once everything has been selected, click Remove duplicates.
- 5. If done correctly, 3 duplicate rows will be found and removed and 604 rows will remain.

# Correct the ratings data

Next, clean up any data that does not make sense. Yelp ratings should be less than 5 and greater than 0. Now, you will determine how many entries are inaccurate and correct them. You can use the COUNTIF function to perform this task.

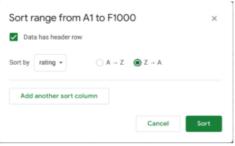

- 1. The COUNTIF function quickly counts how many items in a range of cells meet a given criterion. In cell I2, type =COUNTIF(C:C,">5"). The first entry (C:C) refers to the range where you are counting the data. In this case, the range is the entire rating column (C), which contains the Yelp ratings. The second entry refers to the criterion (>5), and tells the function to count all the values greater than 5.
- 2. Press Enter. You'll notice that the function returns a value of 9. This tells you that your dataset contains 9 entries that have a rating greater than 5.

As a data analyst, it's your job to decide what to do with incorrect values or to ask the dataset owner for advice if you're unsure. In this case, one effective approach would be to search on Yelp for the actual ratings. For this activity, you can just

replace the incorrect ratings with the number 5. An efficient way to replace the ratings is to sort the data numerically from largest to smallest rating.

- 3. Select columns A through F.
- 4. Then, from the menu bar, choose Data, then Sort range, and select Advanced range sorting options.
- 5. In the pop-up window, check the box next to Data has header row. Sort by rating from  $Z \rightarrow A$ . This way, the highest ratings will be listed first.

6. Click Sort. Check out your spreadsheet. At the start of the rating column, you should now find the 9 rows that have incorrect values (rating > 5).

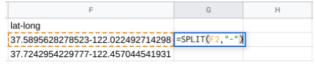

- 7. Next, select the range of cells C2:C10. Press delete to delete the values that are greater than 5.
- 8. Replace all the values with the number 5. In cell C2, type 5. Then, drag the fill handle down to cell C10 to fill the remaining cells with 5.
- 9. After replacing the incorrect ratings with the number 5, you may notice that the new value in cell I2 is 0. The output of the COUNTIF function now reflects the changes in your dataset. This confirms that the rating column no longer contains any values greater than 5.
- 10. FInally, delete the formula from cell I2 since you don't need this information anymore.

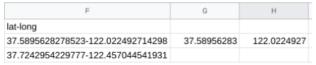

Clean up the latitude and longitude data

Next, clean up the latitude and longitude data by placing each value in a separate column. You can use the SPLIT function to accomplish this task.

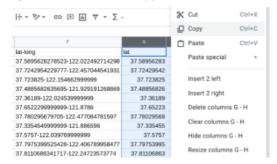

1. The SPLIT function divides text around a specified character or string, and puts each fragment of text into a separate cell in the row. The SPLIT function will split the single lat-long column into two separate columns, one for latitude and the other for longitude. In cell G2, type =SPLIT(F2,"-"). The first entry (F2) refers to the cell where the text is located. The second entry ("-") refers to the fact that you are dividing the text based on the minus sign.

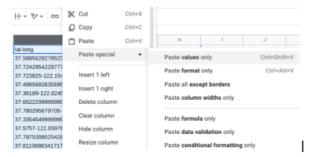

2. Press Enter. The result shows each fragment of text in a different cell.

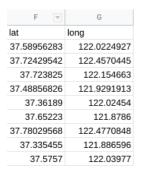

- 3. Select cell G2 again. In cell G2, double-click on the fill handle to split all the remaining lat-long entries.
- 4. Now add column headers to the two new columns (G and H). In cell G1, type lat. In cell H1, type long.
- 5. Next, replace the original lat-long data in column F with the new split entries in columns G and H. Select columns G and H, right-click, and choose Copy.

6. Then, select Column F, right-click, and choose Paste special and Paste values only.

7. Now the new lat column is column F, and the new long column is column G. Adjust the width of the lat column (F) to fit the data by dragging the right boundary of the column heading.

- 8. Next, select column H, right-click, and choose Delete column.
- 9. Finally, the longitude values should be negative so that they are accurate coordinates for mapping. To make the values in the long column negative, multiply them by -1. In cell H2, type =G2\*-1. The asterisk is the operator for multiplication. Press Enter. 10. Still in cell H2, double-click on the fill handle to fill in the rest of the values.
- 11. Next, add a column header. In cell H1, type: long.
- 12. Now, replace the longitude data in column G with the new data in column H. Select column H, right-click, and choose Copy.
- 13. Select Column G, right-click, and choose Paste special and Paste values only.
- 14. Then, select column H, right-click, and choose Delete column.

Columns F and G should look like this:

F	G
lat	long
37.58956283	-122.0224927
37.72429542	-122.4570445
37.723825	-122.154663
37.48856826	-121.9291913
37.36189	-122.02454
37.65223	-121.8786
37.78029568	-122.4770848
37.335455	-121.886596
37.5757	-122.03977

Now your data is cleaner, clearer, and easier to use.

## Confirmation and reflection

Which of the following functions divides text around a specified character or string and puts each fragment of text into a separate cell in the row?

- The SPLIT function
- The COUNTIF function
- The TRIM function
- The CONCATENATE function

## ✓ Correct

The SPLIT function divides text around a specified character or string, and puts each fragment of text into a separate cell in the row. Spreadsheet functions are useful tools for data cleaning, and knowing how to use functions effectively is a key part of every data analyst's skill set.

- 2. In the text box below, write 2-3 sentences (40-60 words) in response to each of the following questions:
- As a data analyst, why is it important for the data you present to be readable, accurate, and visually appealing?
- How can spreadsheet functions help you clean data more efficiently and effectively?

Importance of Readable, Accurate, and Visually Appealing Data:

For a data analyst, data must be readable, accurate, and visually appealing to ensure stakeholders can understand and trust the insights drawn from it. Clear and well-presented data allows for faster, more informed decision-making and minimizes the risk of errors in interpretation.

How Spreadsheet Functions Aid Data Cleaning:

Spreadsheet functions, like COUNTIF and SPLIT, enable efficient data cleaning by automating repetitive tasks, quickly identifying errors, and restructuring data as needed. These tools save time and ensure consistency, allowing analysts to focus on analysis rather than manual data adjustments.

## 

Congratulations on completing this hands-on activity! In this activity, you used spreadsheet functions to clean "dirty" data in a spreadsheet.

Cleaning data is an important part of the data analysis process. If data analysis is based on bad or "dirty" data, it may be biased, erroneous, and uninformed. Knowing how to effectively use spreadsheet functions to work with data is an essential skill for every data analyst. In upcoming activities, you will continue to learn more about spreadsheet functions and how they can help you analyze your data
